### Practical Functional JavaScript Oliver Steele

Oliver Steele Ajax Experience Wednesday, I October 2008

### **Teasers**

- AJAX is all about waiting for someone\*, and remembering what you were going to do when they got back to you.
- Functions : interactions :: objects : domains
- You didn't really want threads anyway. (Most of the time.)
- $^{\star}$   $\,\,$  user, web server, other server, wall clock, plugin

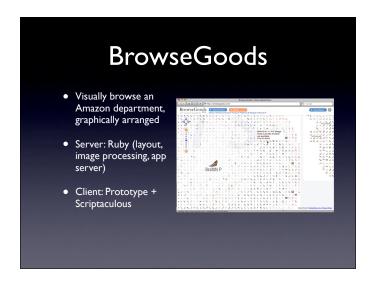

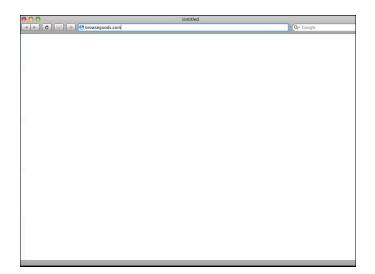

# About You Raise your hand if you know\*: Closures Ruby / Smalltalk XHR / AJAX An AJAX framework (Prototype / jQuery / ...) Threads

### Agenda Some Context Callbacks Case Studies Threaded Callbacks MVC on the Client Registered Callbacks Order & Serializing Fundamentals Retries, Guards, Timeouts Perspectives on Function Closures (review) Q&A Making Functions Decorating Functions Some Idioms

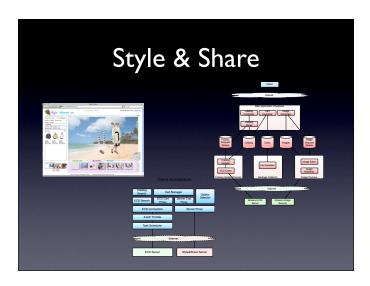

# Non-Agenda Comet, Bayeux, Gears Frameworks\* Theory (this isn't your Monad or CPS fix) Security (standard practices apply) This talk should help you understand their implementation and use, but doesn't explore their APIs in any depth

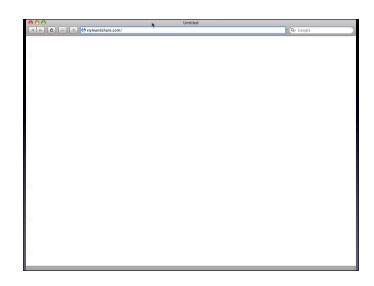

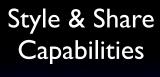

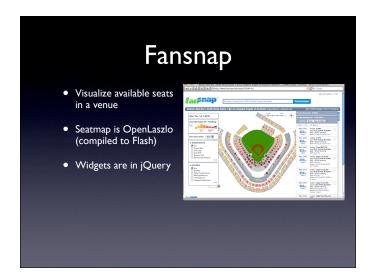

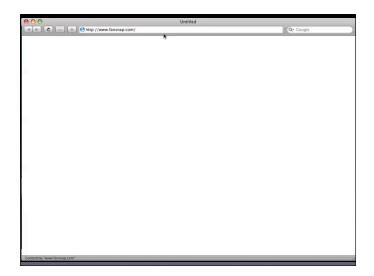

- Retry with exponential backoff and failover
- Explicit queues to control serialization order
- Background prefetch for catalog items
- Multiple queues to prioritize user interaction

### FanSnap Capabilities (Seatmap)

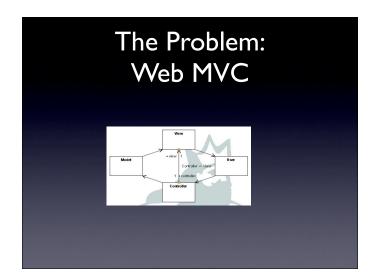

- Two-way asynchronous communication between the Flash plugin and the HTML
- Asynchronous communication between the Flash plugin and the server
- Again, initialization is particularly challenging

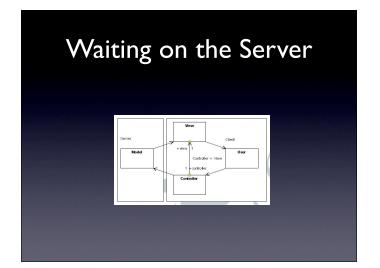

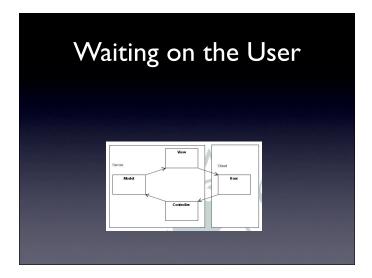

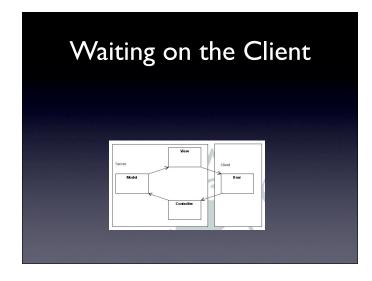

### Webtop Calendar Capabilities (Data Model)

- Synchronizes local model with server model
- Local model is cache: some operations update it; others invalidate it
- Race conditions, where prefetch overlaps operations that invalidate the cache

Function Fundamentals

### What is a Function?

- Math: rule that maps inputs to outputs
- Computer science: abstracted computation with effects and outputs
- Software engineering: one of several units for documentation, testing, assertions, and analysis
- Source code: unit of source text with inputs and outputs
- Runtime: invocable parameterized behavior

```
function callback(x) {
   log('received "' + x + '"');
}

function request() {
   $.get('/request', callback);
}

request();
Results

Results

$.get('/request', callback);
}
```

```
function makeConst1() {
    return function() { return 1; }
}

function constla() { return 1; }
var constlb = function() { return 1
var constlc = makeConstl();

log(constla());
log(constlb());
log(constlc());
```

```
var get, set;
function setAccessors() {
    var x = 1;
    get = function() { return x; }
    set = function(y) { x = y; }
}

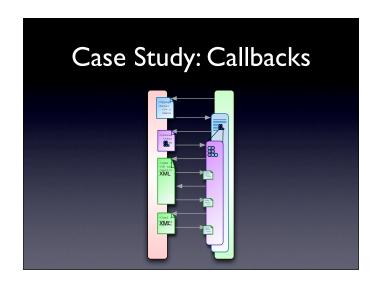

setAccessors();
log(get());
set(10);
log(get());
```

```
// 'this' and 'arguments' are special
function f() {
   logArguments(this, arguments);
}
f();
f('a');
f('a');
f('a', 'b');

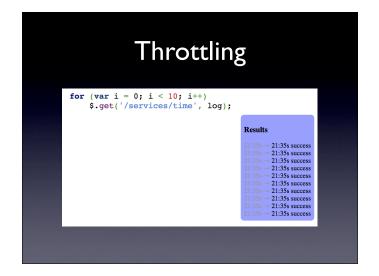

Results

21:35s → this = (object DOMWindow)
21:35s → arguments = [a]
21:35s → this = (object DOMWindow)
21:35s → arguments = [a, b]
```

### Functions are values Functions can be arguments, return values, array elements, property values Functions can be created and "modified" Argument lists can be saved, modified, and replayed

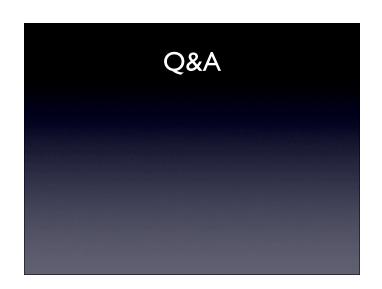

## Callback Scenarii Chained Callbacks Conjunctive-Trigger Callbacks Callbacks Conditional Callbacks Conditional Callbacks Caching Caching Timeouts Retry and Failover

```
$.getWithRetry = function(url, k) {
  var countdown = 10;
  $.ajax({url:url, success:k, error:retry});
  function retry() {
    if (--countdown >= 0) {
        log('retry');
        $.ajax({url:url, success:k, error:retry});
    }
};

$.getWithRetry('/services/error', log);
```

### Functions-as-objects allow separation of concerns Factor how, when, and whether from what Functions are to interaction patterns as objects are to domains

### Thanks!
